MGD	million gallon(s) per day
mt	metric tons
N <sub>2</sub> O	nitrous oxide
N <sub>2</sub> Oe	nitrous oxide equivalent
PE	Professional Engineer
PFCs	perfluorocarbons
Scope 1	direct emissions
Scope 2	indirect emissions
Scope 3	other indirect emissions by contractors
SF <sub>6</sub>	sulfur hexafluoride
USEPA	U.S. Environmental Protection Agency
WBCSD	World Business Council for Sustainable Development
WRI	World Resources Institute

## Executive Summary

Fishbeck, on behalf of the City of Muskegon (City), has prepared this greenhouse gas (GHG) emission inventory for fiscal year (FY) 2022 (July 1, 2021 to June 30, 2022).<sup>1</sup> The City’s goal is to eliminate or off-set their GHG emissions by 2040 without compromising city services.

GHGs are gases in the Earth’s atmosphere that trap heat. They allow sunlight to pass through the atmosphere, but prevent the heat from that sunlight from leaving the atmosphere, causing the earth to warm over time (i.e., climate change). Reducing GHGs is key to mitigating the risk of climate change.

The first step for the City to take toward meeting this goal is to quantify the City’s GHGs, and understand how City operations contribute to GHG emissions (also known as the City’s carbon footprint). This inventory can then be used by the City to manage its GHG risks, identify reduction targets, and participate in voluntary or mandatory GHG reporting programs.

The GHG emissions that were able to be quantified for the governmental operations in FY2022 were approximately **10,337 tons of carbon dioxide equivalent (CO<sub>2</sub>e)**,<sup>2</sup> or **40 ton CO<sub>2</sub>e per full-time equivalent personnel (FTE)**. Approximately 110,000 18-inch-diameter oak trees, or about 65,000 26-inch-diameter oak trees would be required to uptake/off-set the City’s FY 2022 GHG emissions.<sup>3</sup>

Scope 1 and 2 emissions from City operations are direct and indirect GHG emissions, respectively.

**Scope 1 Emissions** (Direct GHG Emissions ) are a result of the following City activities:

- Combustion of fuel or natural gas in facility boilers, furnaces, and generators
- Consumption of fuel oil or gasoline in City-owned/leased vehicles
- Combustion of propane in mobile equipment

**Scope 2 Emissions** (Indirect GHG Emissions) are a result of the following City activities:

- Purchased electricity for facility use.

**Scope 3 Emissions** are other indirect emissions, that result from activities by the City, but are not owned or controlled by the City, such as contractors or employee commuting to work. Scope 3 is an optional reporting category, which was outside of the organizational boundary for this GHG Inventory.

### The greenhouse effect

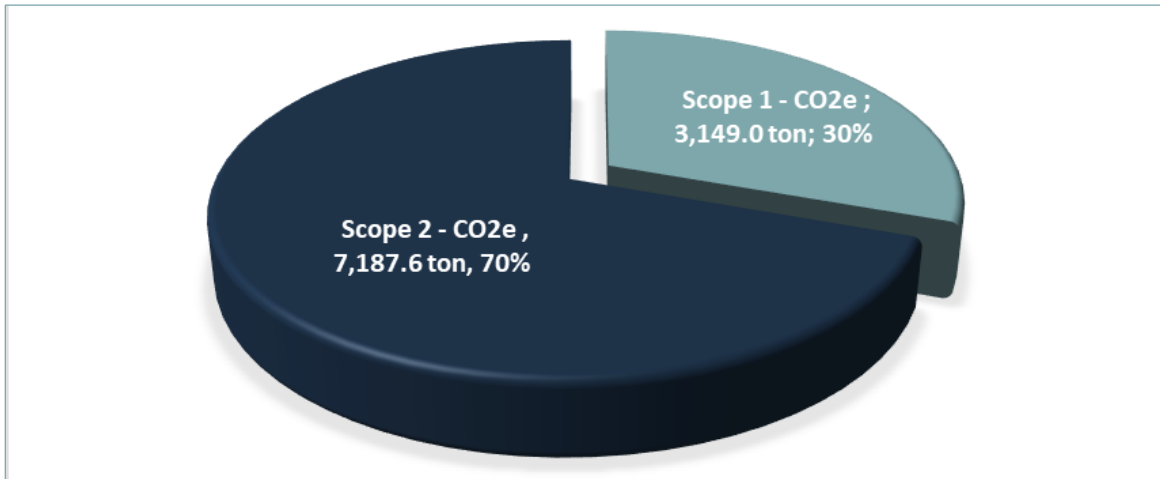

Source: Adapted from U.S. Environmental Protection Agency

<sup>1</sup> FY2022 was selected because the quality of available data would produce the most accurate inventory – at the time of calculation, and it is the year for which the most recent audited financial information was available.

<sup>2</sup> CO<sub>2</sub>e as presented in this report is measured in short tons; a short ton is 2,000 pounds. Picture a cube almost as tall, wide, and long as a telephone pole; that would hold approximately 1 short ton of CO<sub>2</sub>e. For simplicity, we use tons of CO<sub>2</sub>e herein.

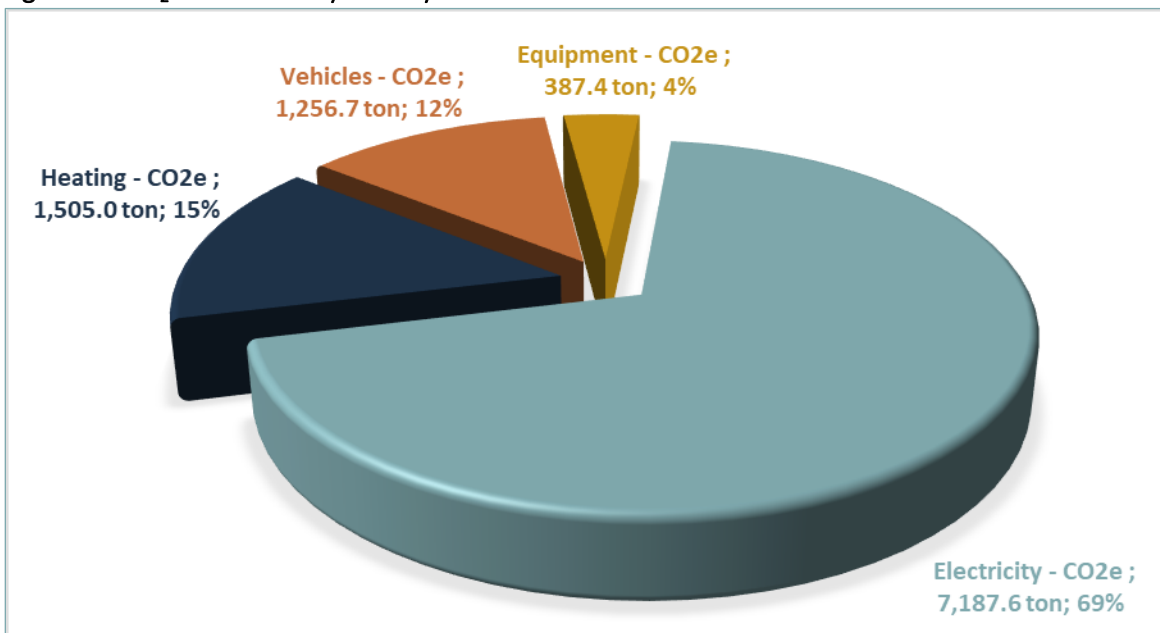

<sup>3</sup> My tree benefits - itreetools.org

Figure 1 – Muskegon CO<sub>2</sub>e Emissions

The majority of the City’s GHG emissions (approximately 70 %) result from purchased electricity (or Scope 2 Emissions)’ more than 40% of the purchased electricity is for the water filtration plant.

Figure 2 – CO<sub>2</sub>e Emissions By Activity

The City followed the GHG Emission Inventory Protocol established by the World Resources Institute (WRI) and the World Business Council for Sustainable Development (WBCSD) as presented in the *Greenhouse Gas Protocol: Corporate Accounting and Reporting Standard* (WRI and WBCSD, September 2001) and further refined in the *Greenhouse Gas Protocol: A Corporate Accounting and Reporting Standard, Revised Edition* (WRI and WBCSD, 2015), hereafter referred to as the *GHG Protocol*.<sup>4</sup> These protocols were designed to address the Kyoto Protocol – a treaty developed to set binding obligations on industrialized nations to reduce their impacts on climate change. Additional tools from the USEPA were used, including the *Local Greenhouse Gas Inventory Tool* and *Center for Corporate Climate Leadership*.

<sup>4</sup> Note - we chose to report in English units, (i.e., pounds and short tons) in lieu of metric tonnes used in the protocol. A metric ton is approximately 2,204 pounds.

The GHG Protocol is the most widely used international accounting tool to quantify and manage GHG emissions. It is the framework used by most multinational companies, as well as by The Climate Registry (currently used in select areas of the U.S., Mexico, and Canada), the European Union Emission Trading Scheme, and the International Standards Organization.

## 1.0 Muskegon GHG Emission Philosophy

The City is committed to reducing its carbon footprint while continuing to provide its residents with efficient and superior infrastructure and services. In April 2023, the City Commission passed a resolution declaring the City's commitment to climate action initiatives and to combat the impact of climate change on the community and planet. The City is dedicated to reducing the risks of climate change by implementing actions that save money, improve productivity, and lower GHG emissions. The City intends to reduce its organizational GHG emissions through deliberative budget, policy, and administrative actions.

In an effort to reduce GHG emissions, the City must first understand its current GHG footprint and the drivers of those emissions. Therefore, the City Commission directed an organization-wide GHG Inventory which will be used by the City to set target reductions with the goal of eliminating the City's GHG emissions by 2040.

## 2.0 Introduction

The risk of climate change to governmental operations may include:

- Increased frequency and intensity of extreme weather, which can disrupt critical infrastructure, such as power grids, transportation systems, and water supply networks, leading to service disruptions and economic losses.
- Changes in Lake Michigan water levels may become more extreme. Warming temperatures can cause algal blooms and are more hospitable for invasive species. While heavy rainfall events can overwhelm drainage systems and cause water contamination. These issues can impact water supply, sanitation, and public health in cities. Alternately, droughts can lead to water scarcity.
- Rising temperatures can lead to increased heat stress, especially in urban areas. Heatwaves pose health risks, particularly for vulnerable populations, such as the elderly and those with pre-existing health conditions. This can strain cities first response services.
- Climate change can impact agricultural productivity and food supply chains, leading to food shortages and price volatility. Cities that are heavily reliant on imported food may face challenges in ensuring food security.
- Climate change-related disruptions can have significant economic consequences for cities. Damage to infrastructure, increased insurance costs, and decreased productivity due to extreme weather events can result in financial losses. Additionally, cities that rely on industries vulnerable to climate change, such as tourism or agriculture, may experience economic downturns.

Source: *The Signs of Climate Change | A Student's Guide to Global Climate Change | USEPA*

A 2021 U.S. Environmental Protection Agency (USEPA) analysis indicated that racial and ethnic minority communities are particularly vulnerable to the greatest impacts of climate change which can exacerbate existing social inequalities.<sup>5</sup> Vulnerable populations, such as low-income communities and marginalized groups, may be disproportionately affected due to limited resources and access to services. This can lead to social unrest and increased social disparities within cities.

To mitigate the risks of climate change, cities need to develop climate adaptation and resilience strategies, invest in infrastructure upgrades, and implement policies to reduce GHG emissions. “Having a climate-resilient economy—one that can withstand or recover quickly from climate impacts in the short and long terms—is essential to a community’s well-being. Starting to plan now with climate and economic resilience in mind will help the community and its businesses protect themselves against short-term shocks such as storms, reduce the need (and cost) to recover from a shock, incorporate economic resilience into other planning efforts, and get a jump-start on pursuing new opportunities that might arise as the climate changes.”<sup>6</sup>

Collaboration between local governments, local businesses and the community they serve is crucial to effectively address the risks of climate change to City operations. One of the first steps is to develop a framework for accounting and reporting GHG emissions resulting from City operations and activities. The purpose of the inventory is to provide baseline information, which will allow the City to make informed and effective policy decisions.

This document may be updated periodically as technologies evolve and budgets warrant. It is a basis upon which benchmarking can be further defined. The document is intended to allow the City leaders to formulate opportunities and select strategies the City wishes to pursue in striving to reduce its GHG emissions. For the first time, the City has gathered and analyzed data to provide a comprehensive understanding of GHG for all City facilities and fleet. Development of a baseline GHG inventory will allow the City to extend their history of leadership in environmental and economic sustainability and bring benefits to the local community for many years.

City team members responsible for providing information and data for this effort included:

- Peter Wills, Director of Government Relations & Strategic Operations
- Dan VanderHeide, PE, Public Works Director
- Jacqui Erny, Administrative Supervisor
- Jill J. Hernandez, Department of Public Works

## 3.0 Methodology

### 3.1 Organizational Boundaries

For the purposes of this GHG inventory, the City focused on its City operations, fleet, and equipment, as the City has both financial and operational control of these assets. City operations include City Hall, the Department of Public Works (DPW), Water Filtration Plant, Trinity Health Arena, three fire stations, police services, four cemeteries, 40 parks, and half of the Harvey Pump Station, as well as the associated 5 million gallon reservoir, 3 elevated water tanks, and 18 sanitary sewer lift stations. The following operations and activities are included in the FY2022 analysis:

- City-owned buildings
- Emergency generators
- Fleet vehicles

---

<sup>5</sup> [EPA Report Shows Disproportionate Impacts of Climate Change on Socially Vulnerable Populations in the United States](#)

<sup>6</sup> Planning Framework for a Climate-Resilient Economy, USEPA, April 2016.

- Movable bridges
- Lighting infrastructure (includes street lights and parking facilities)
- Pump stations
- Water management infrastructure
- Equipment

GHG Emissions were summarized into several departments and Activities. A list of City departments and activities, along with GHG emissions is provided in Table 1.

The following activities were not included in the analysis due to the challenges in collecting the necessary data, or a lack of available data to support robust emissions calculations:

- Air travel
- Travel for City business in non-City vehicles
- Losses from heating, ventilating, and air conditioning (HVAC) equipment in City-owned or -operated buildings

If additional data is collected, GHG emissions from the activities listed above will be included in future inventories.

**Table 1 - City Departments/Activities and GHG Emissions**

Account/Department	Budgeted FTEs	CO <sub>2</sub> e (ton)	CO <sub>2</sub> e (tons/FTE)
Arena	6.00	2,186.4	364.4
Cemeteries	2.00	71.9	35.9
City Hall	31.55	718.7	22.8
Community & Neighborhood Services	5.30	2.6	0.5
Department of Public Works	8.75	7.6	0.9

Street Lighting	0.00	644.9	--
Traffic Services	7.20	17.8	2.5
Water Filtration Plant	12.15	3,661.1	301.3
Water & Sewer	25.85	539.4	20.9
<b>Total</b>	<b>258.50</b>	<b>10,336.7</b>	<b>40.0</b>

### 3.1.1 Water Management Infrastructure

The City's Water Filtration Plant is a 40 million gallon per day (MGD) capacity drinking water treatment facility located on the Lake Michigan shoreline near Pere Marquette Park.

The drinking water filtered through the City's plant serves a population of approximately 90,000 in the City and several neighboring communities, including: Dalton, Fruitland, Fruitport, Laketon, and Muskegon Townships, as well as the cities of North Muskegon, Norton Shores, and Roosevelt Park. Within these communities, the 12 MGD daily average (20 MGD peak) production is used by residential, commercial, and industrial users, in addition to supplying water to fire hydrants.

One of the largest expenses encountered in water treatment is electricity, the majority of which is used by the large pumps used to pump water to the communities the plant serves. The electricity purchased for the water treatment facility contributes to the City's indirect (or Scope 2) emissions. The Water Filtration Plant uses nearly 5 million kilowatt hours per year (kWh/yr). Because the Water Filtration Plant needs to run continuously, two large diesel generators are able to power the plant during power outages to ensure an uninterrupted supply of water. The diesel generators contribute to the City's direct (or Scope 1) emissions.

The water filtration plant is the single largest source of GHG emissions for the City; however, the emissions generated are also the result of servicing nearby communities. It is the City's intention to perform an analysis separating the GHG emissions generated to service the City's population from those generated to service neighboring communities.

## 3.2 Protocol Selection

The City followed the GHG Emission Inventory Protocol established by the World Resources Institute (WRI) and the World Business Council for Sustainable Development (WBCSD) as presented in the *Greenhouse Gas Protocol: Corporate Accounting and Reporting Standard* (WRI and WBCSD, September 2001) and further refined in the *Greenhouse Gas Protocol: A Corporate Accounting and Reporting Standard, Revised Edition* (WRI and WBCSD, 2015), hereafter referred to as the *GHG Protocol*. These protocols were designed to address the Kyoto Protocol – a treaty developed to set binding obligations on industrialized nations to reduce their impacts on climate change. Additional tools from the USEPA were used, including the *Local Greenhouse Gas Inventory Tool* and *Center for Corporate Climate Leadership*.

The GHG Protocol is the most widely used international accounting tool to quantify and manage GHG emissions. It is the framework used by most multinational companies, as well as by The Climate Registry (currently used in select areas of the U.S., Mexico, and Canada), the European Union Emission Trading Scheme, and the International Standards Organization.

The 6 GHGs identified in the [Kyoto Protocol](#), include:

- Carbon dioxide (CO<sub>2</sub>)
- Methane (CH<sub>4</sub>)
- Nitrous oxide (N<sub>2</sub>O)
- Hydrofluorocarbons (HFCs)
- Perfluorocarbons (PFCs)
- Sulfur hexafluoride (SF<sub>6</sub>)

Of these gases, City activities result predominately in emissions of CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O, which are released by the combustion of fossil fuels. The remaining gases in the Kyoto Protocol are man-made and are generally released through specific refrigeration and building cooling equipment as well as energy transmission activities.

Losses from refrigeration and building cooling equipment in City buildings were not evaluated as part of this GHG inventory.

A verification process is part of the GHG Protocol, developed to ensure that the data, assumptions, and procedures used to develop the inventory are reliable and defensible. The City has developed this inventory with the intent that it could be verified by a third-party auditor.

### 3.2.1 Emission Sources

Scope 1 and 2 emissions from City operations are direct and indirect GHG emissions, respectively.

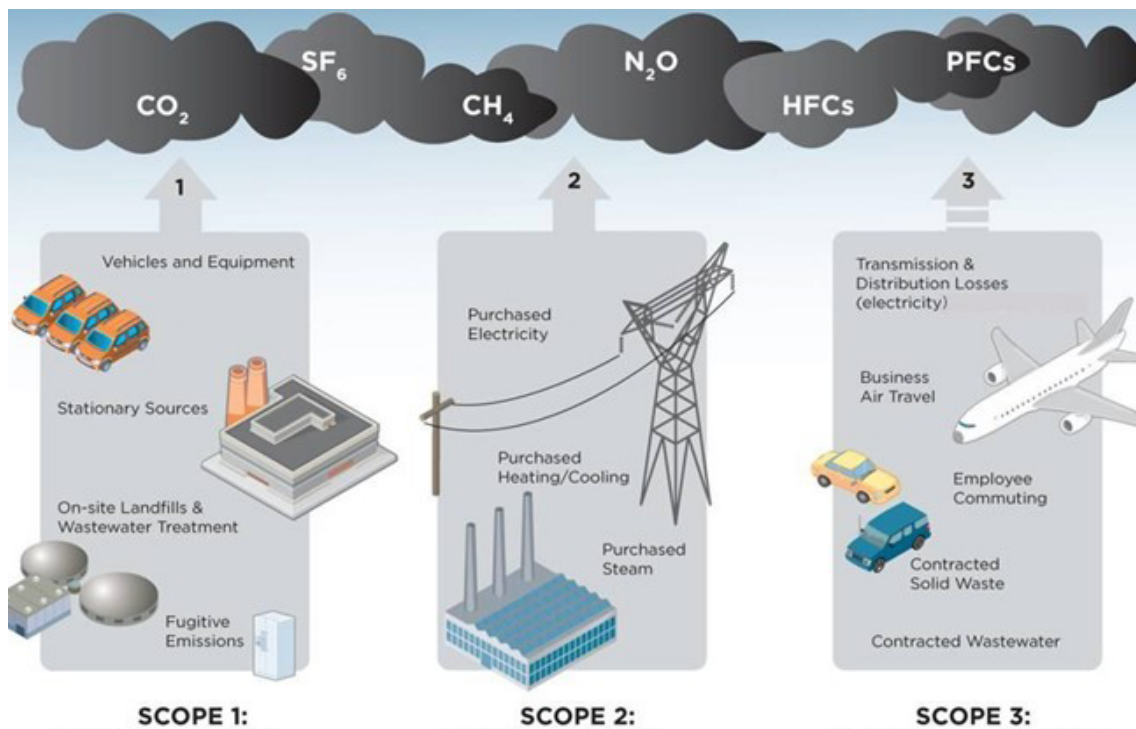

**Scope 1 Emissions** (Direct GHG Emissions ) are a result of the following City activities:

- Combustion of fuel or natural gas in facility boilers, furnaces, and generators
- Consumption of fuel oil or gasoline in City-owned/leased vehicles
- Combustion of propane in mobile equipment

**Scope 2 Emissions** (Indirect GHG Emissions) are a result of the following City activities:

- Purchased electricity for facility use.

**Scope 3 Emissions** are other indirect emissions by contractors. Scope 3 is an optional reporting category that allows for the accounting of all other indirect emissions which are a consequence of the activities of the City, but occur from sources not owned or controlled by the City. Some examples of Scope 3 activities are extraction and production of purchased materials, transportation of purchased fuels, and use of sold products and services. Scope 3 emissions were outside of the organizational boundary for this GHG inventory.

Source: <https://www.epa.gov/greeningepa/greenhouse-gases-epa>

### 3.2.2 Data Sources

The data used to calculate Scope 1 and Scope 2 GHG emissions came from sources and matrices already recorded and maintained by City Facilities personnel or by contacting utility companies. These data include:

- Electricity consumption
- Natural gas consumption
- Fuel oil consumption
- Vehicle fuel consumption

**3.2.3 Reporting Year**

A primary aspect of the GHG emissions inventory process is the requirement to select an appropriate baseline year with which to compare emissions among time periods. Although the City signed the *U.S. Council of Mayors Climate Protection Agreement*, which recommends using 1990 as the baseline year, this would prove difficult for the City because the quality of available data would not produce an accurate inventory.

The City established FY2022 as the baseline year. At the time the baseline year was selected/calculations performed, FY2022 was the year for which the most recent **audited** financial information was available.

**3.2.4 Emission Factors**

Emission factors for the most common emission sources at City facilities are from the *USEPA Center for Corporate Climate Leadership GHG Emission Factors Hub* (modified September 2023). Emission factors included in the hub are :

- Stationary combustion sources
- Mobile combustion sources for on-road vehicles (1973 to 2020)
- Mobile combustion sources for non-road vehicles
- Emissions & Generation Resource Integrated Database (eGRID 2021)

All GHGs are calculated separately and converted to CO<sub>2</sub>e on the basis of their global warming potential (GWP) provided in The Intergovernmental Panel on Climate Change (IPCC), Fourth Assessment Report, 2007. The GWPs were developed to compare the global warming impacts of different gases relative to CO<sub>2</sub>. The larger the GWP the more that gas warms the earth when compared to CO<sub>2</sub>. For instance, the GWP for N<sub>2</sub>O is 25 times that of CO<sub>2</sub>, and the GWP of CH<sub>4</sub> is 298 times that of CO<sub>2</sub>. All GHGs in this analysis are presented as their CO<sub>2</sub>e value. A summary of the City’s GHG emissions is provided in Appendix 1.

Emission factors used in the calculations are summarized in the facility workbooks developed for the City and are presented in Appendix 2.

**3.2.5 Emission Calculations**

In general, emissions were calculated by multiplying the fuel usage or electric consumption by the emission factors described in 3.2.4. For example, the CO<sub>2</sub> emissions from electric usage at the Terrace St Fire Station was calculated as follows:

$$CO_2 \left( \frac{lb}{yr} \right) = 576.6 \frac{MWh}{yr} \text{ of Electric Used } x 1,214.1 \frac{lb CO_2}{MWh}$$

$$CO_2 \text{ emissions } \left( \frac{lb}{yr} \right) = 699,807.24 \frac{lb}{yr}$$

All GHG emissions were then converted to CO<sub>2</sub>e using global warming potentials as follows:

$$CO_2e \left( \frac{ton}{yr} \right) = \frac{\left( CO_2 \left( \frac{lb}{yr} \right) x 1 + CH_4 \left( \frac{lb}{yr} \right) x 25 + N_2O \left( \frac{lb}{yr} \right) x 298 \right)}{2000 \frac{lb}{ton}}$$

Emissions were calculated in an Excel-based workbook, which was populated with the City’s raw consumption data and applicable emission and conversion factors. The complete workbook was provided to the City under separate cover.

### 3.2.6 Renewable Energy Credits and Biofuels

Renewable energy and biofuels were not evaluated as part of the GHG inventory.

The City purchases energy through Consumers Energy, which has a program called the *Green Generation Program (GGP)*.<sup>7</sup> The GGP is governed by tariff which is approved by the Michigan Public Service Commission (MPSC). According to the 2019 GGP Terms and Conditions, Consumers Energy purchases renewable energy from a number of qualified renewable generating facilities in the state of Michigan. Supply for the GGP is produced in Michigan and is made up of approximately 70% wind and 30% biomass. The City does not currently participate in the GGP. In the future, should the City elect to participate in the GGP or other renewable energy credit, then GHG emissions from electricity usage may be off-set.

Biofuels, such as biodiesel and gasoline ethanol blends, have historically been considered *biogenic emissions*, and therefore carbon neutral. However, according to the Climate Disclosure Project (CDP) Biofuels Technical Note,<sup>8</sup> *It is challenging to draw overarching conclusions about the environmental impacts of biofuels.*

The CDP suggests that sources should mitigate negative impacts by purchasing sustainably produced (and certified) biofuels. For the City's inventory, biofuels were not included in fuel purchase records; however, should the City determine that purchasing biofuel in lieu of non-biofuels to mitigate the City's future carbon impact, the source of the biofuels should be carefully evaluated.

Source: <https://www.epa.gov/air-research/energy-and-environment-research>

## 4.0 Assumptions and Uncertainty Assessment

Generally, emissions are based on the purchase records and the assumption that all materials were processed, consumed, wasted, or emitted. However, for certain activities, site-specific knowledge of the activity and/or emission factors are used to determine actual emissions. For this inventory, the assumption is that the information provided by the City is accurate and verifiable through any audit process. The quality of this GHG inventory is reliant on this assumption.

The most reliable data available was used and this inventory fairly represents the City's GHG emissions; however, there are uncertainties associated with the emission estimates. Select estimates, such as those for CO<sub>2</sub> emissions from energy-related activities, are considered to have low levels of uncertainty. For other categories of emissions, such as the emissions from vehicle use, increases the uncertainty level associated with the estimates presented (e.g., lack of data or details regarding the vehicle make/model, driving habits surface roads/highway, etc.). As part of this evaluation, the City provided vehicle fuel usage and mileage based on data reported to the City's fuel supplier Van Manen. CO<sub>2</sub> emission factors from vehicles are determined based on fuel usage, while CH<sub>4</sub> and N<sub>2</sub>O emission factors are based on mileage. Fuel usage records are considered accurate, as they are recorded using the City's fuel pump meters. For vehicle mileage, the records rely on data entry by employees. In some instances, vehicle mileage data entry appeared to have typographical errors. The City has 159 vehicles and it was not possible to manually assess each vehicles odometer readings; therefore, the City elected to calculate emissions of CH<sub>4</sub> and N<sub>2</sub>O based on gallons of fuel multiplied by the emission factors in gram per mile converted to gram per gallon, based on USEPA Community GHG Inventory Tool, which provides an average mile per gallon for different vehicle types. Additionally, emission factors for vehicles were currently only available through model year 2020.

<sup>7</sup> [Microsoft Word - 1605 3-2018 \(consumersenergy.com\)](#)

<sup>8</sup> [CDP-technical-note-on-biofuels.pdf](#)

For vehicles with model years 2021 to 2023, the emission factors for model year 2020 were used. In addition, for vehicles where the model year was not readily available, the City elected to use model year 2015 emission factors. For City vehicles, it should also be noted that calculating emissions based on mileage for certain vehicles may have inherent uncertainties. For example, many City owned vehicles, such as Police and Maintenance vehicles may idle for longer periods of time than the vehicles used to develop the emission factor averages in the USEPA emissions hub.

As this is the first year the City has developed a GHG inventory, the City can work toward improving the quality and accuracy of the data collected and used for future inventories. This includes more accurate mileage record keeping and may include developing a data base for each new vehicle purchased or leased, which includes the manufacturer’s emission related data for the specific vehicle.

## 5.0 Findings

### 5.1 Muskegon GHG Inventory

#### 5.1.1 GHG Emissions

The City’s GHG emissions from the activities for which there was adequate data are **10,336.67 tons** of CO<sub>2</sub>e. A summary of the GHG emissions from City Departments is presented in Table 2

**Table 2 – Greenhouse Gas Emissions by Department**

Account/Department	CO <sub>2</sub> (ton)	CH <sub>4</sub> (lb)	N <sub>2</sub> O (lb)	CO <sub>2</sub> e (ton)	%Scope 1	% Scope 2
Arena	2,175.30	329.30	46.58	2,186.36	25%	75%

<b>Total</b>	<b>10,277.33</b>	<b>1,524.37</b>	<b>270.35</b>	<b>10,336.67</b>	<b>30%</b>	<b>70%</b>

City Emissions can be categorized as Scope 1 – Direct Emissions or Scope 2 – Indirect Emissions. The emissions illustrated in Figures 3 to 5 present the Scope 1 (Heating, Vehicles, Equipment) emissions by department.

Figure 3 – Scope 1 (Heating) Emissions by Department

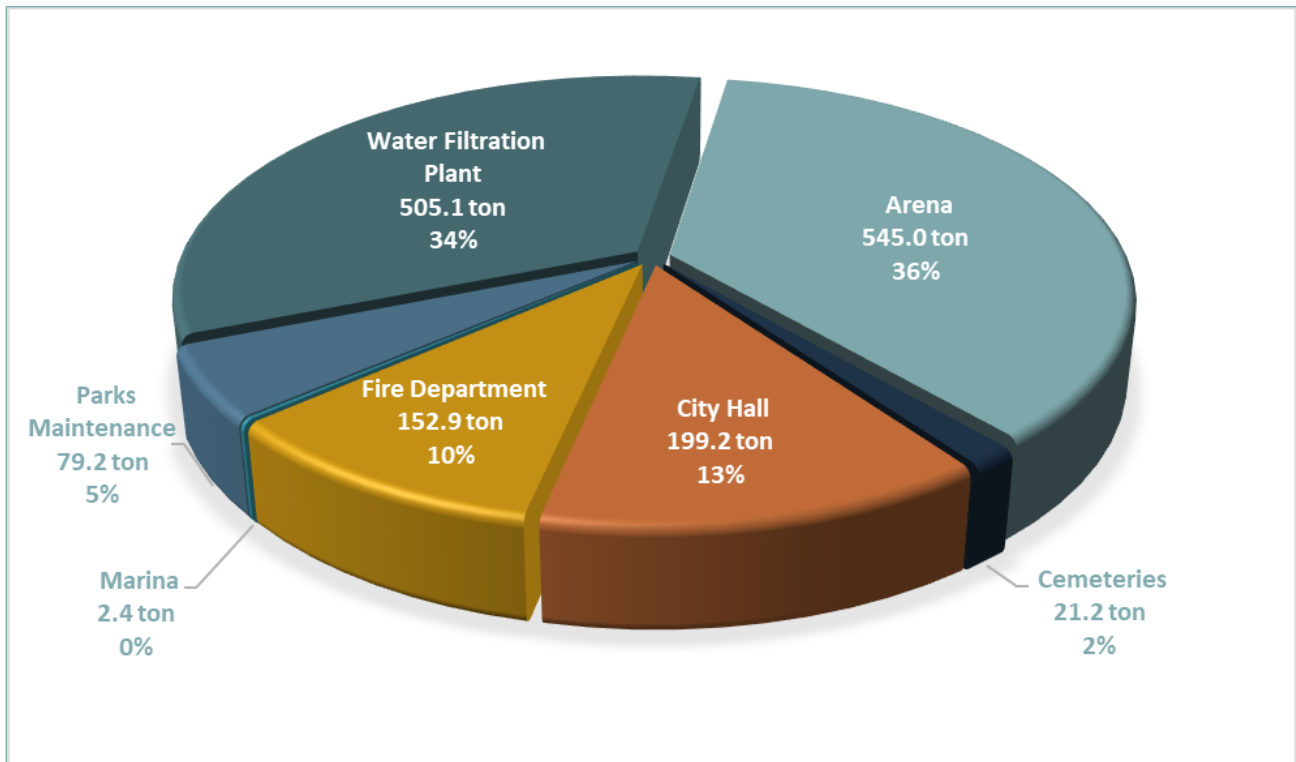

Figure 4 – Scope 1 (Vehicles) Emissions by Department

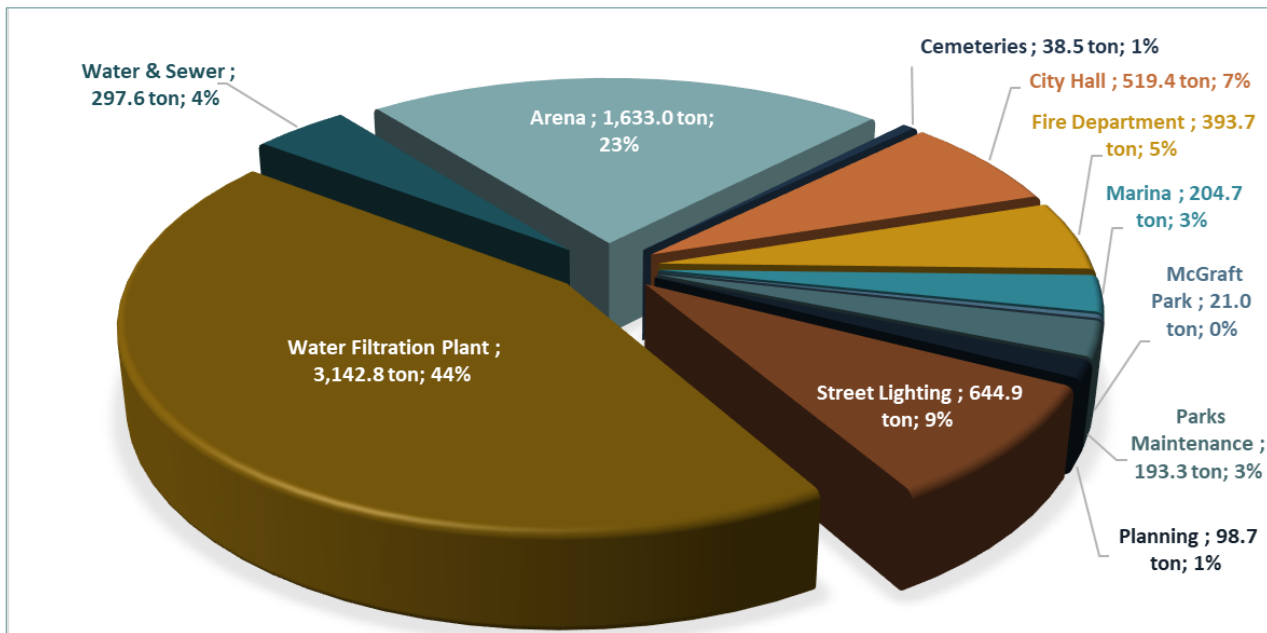

Figure 5 – Scope 1 (Equipment) Emissions by Department

The GHG from purchased electricity accounts for 70% of the City’s emissions; more than 40% of the emissions are from the water filtration plant. The emissions illustrated in Figure 6 present the Scope 2 (electricity) emissions by department.

Figure 6 – Scope 2 (Electricity) Emissions by Department

Based on the data available, GHG emissions from vehicles account for 12% of the City’s emissions. As illustrated in Figure 4, emissions are from the combustion of gasoline and diesel fuel.

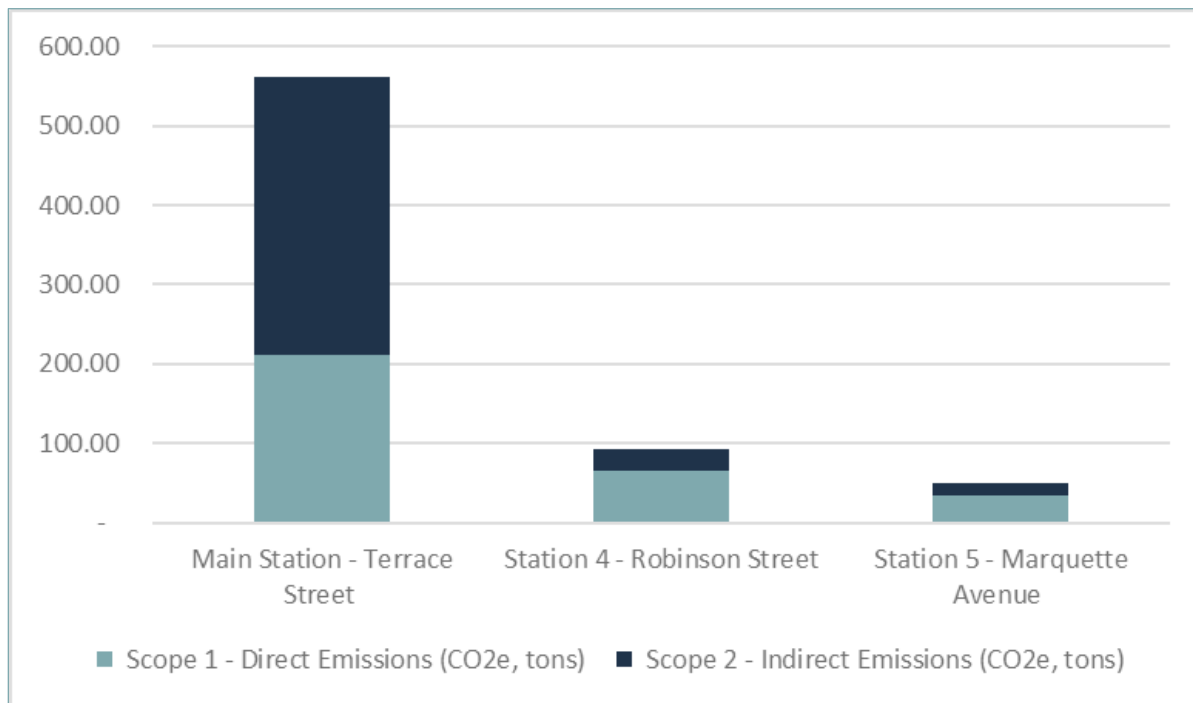

Figure 7 – Sources of CO<sub>2</sub>e Vehicle Emissions by Fuel Type

The City has three Fire Stations, emissions from each of the fire stations are provided in Figure 8.

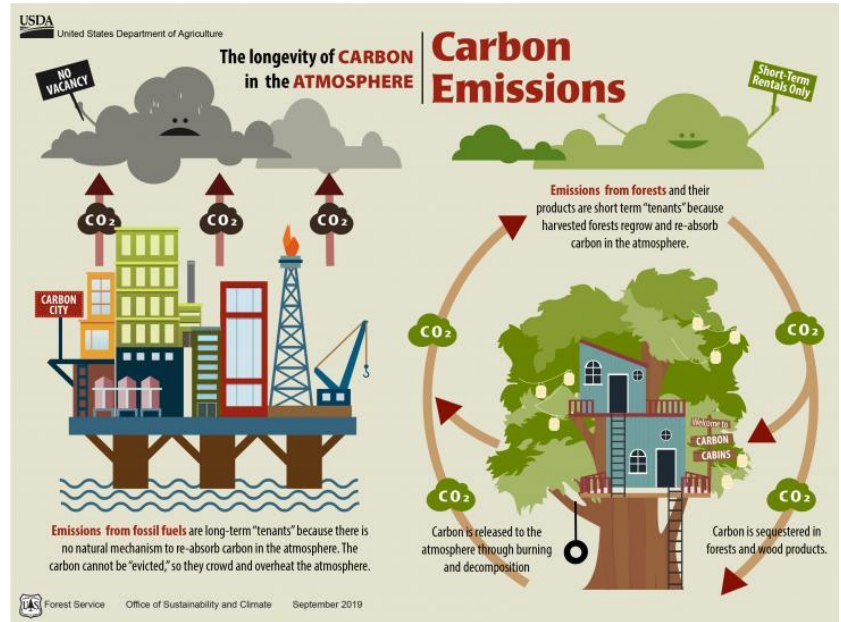

Figure 8 – CO<sub>2</sub>e Emissions by Fire Department

## 6.0 Carbon Sinks

Now that a baseline of the City’s GHG emissions has been established, future inventories can use the City’s carbon sinks to counteract GHG emissions. **Carbon sinks** are *features that naturally remove carbon from the atmosphere for temporary storage, such as trees and compost yards*. Across the City, thousands of trees form a canopy which serves as a carbon sink. This canopy is primarily made up of oak trees, which are one of the most effective deciduous trees for absorbing carbon. This canopy is supplemented by the City’s compost yard. This yard is primarily non-residential; however, it is open to residents for a fee. The compost at the yard is composed of wood and leaf waste and lawn clippings. As the organic materials in the compost yard break down, they pull carbon from the atmosphere and trap it in the soil.

According to itreetools.org, which is a peer-reviewed software suite from the USDA Forest Service that provides urban and rural forestry analysis, a 30-inch-diameter northern red oak tree located in Muskegon and in good condition can absorb an equivalent of 4.5 tons of CO<sub>2</sub> over 20 years. Using the itreetools.org website, Fishbeck estimated the number of red oak trees it would take to absorb the City’s GHG emissions for FY2022.

**Table 3 – Red Oak CO<sub>2</sub> Sequestration**

Diameter at DBH (inches)	Red Oak Estimated Age (years)	CO <sub>2</sub> Sequestration (lb/tree/yr)	No. of Trees Needed to Off-Set
10.00	40.00	83.86	246,522.01
12.00	48.00	107.79	191,792.70
14.00	56.00	134.02	154,255.60
16.00	64.00	161.89	127,699.89
18.00	72.00	191.28	108,078.92
20.00	80.00	222.10	93,081.20
22.00	88.00	254.24	81,315.21
24.00	96.00	287.71	71,854.77
26.00	104.00	322.36	64,131.21
27.00	108.00	340.13	60,780.69
28.00	112.00	358.17	57,719.34
30.00	120.00	395.09	52,325.64

MyTree (itreetools.org)

Diameter at breast height, or DBH, is the standard for measuring trees. DBH refers to the tree diameter measured at 4.5 feet above the ground

Growth Factor for Red Oak per DBH 4.00

2022 GHG Emissions 20,673,335.59 lb CO<sub>2</sub>e

The i-Tree website also provides a canopy evaluation for certain areas, which included Muskegon. The following graphics represent the output for the Muskegon area.<sup>9</sup>

## OurTrees Benefits

### Trees in Muskegon, MI

**Serving Size:**  
 20.33% tree canopy on 1,849 acres  
 39.72% impervious surfaces over 3,612 acres  
**Total benefits for this year: \$809,564**

Annual values:	
Carbon Dioxide Uptake	\$300,358
Carbon Sequestered	1,761 tn
CO <sub>2</sub> Equivalent <sup>1</sup>	6,457 tn
Storm Water Mitigation	\$246,271
Runoff Avoided	28 MG/yr
Rainfall Intercepted	142 MG/yr
Air Pollution Removal	\$262,935
Carbon Monoxide	1,503 lb/yr
Ozone	92,352 lb/yr
Nitrogen Dioxide	3,902 lb/yr
Sulfur Dioxide	3,390 lb/yr
PM <sub>2.5</sub>	4,816 lb/yr
Values are totals to date:	
Carbon Dioxide Uptake	\$11,302,501
Carbon Storage	66,271 tn
CO <sub>2</sub> Equivalent <sup>1</sup>	242,992 tn

Benefits are based on USDA Forest Service research and are meant for guidance only. Visit [www.itreetools.org](http://www.itreetools.org) to learn more. Get more data at [i-Tree Landscape!](#)

## OurTrees Story

The impacts of tree benefits can be hard to grasp. Below are some real-world examples of how trees work hard for our community.

### Trees in Muskegon, MI

*Trees lower air temperature and absorb water, while impervious areas do the opposite.*

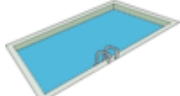

**Trees shade an area equivalent to 1,399 professional football fields!** 

 **The land area covered by impervious surfaces – typically buildings and pavement – is like a 5.6 square mile parking lot.**

### Annual Tree Benefits for Muskegon, MI

**Sequestering carbon as wood in trees counteracts the CO<sub>2</sub> emissions of 1,263 gasoline powered passenger cars.** 

 **The filtration and removal of air pollution by the leaves of trees is estimated to reduce acute respiratory symptoms and exacerbated asthma by 35 incidents. This also prevents the loss of 6 school day(s) and 1 work day(s).**

**Rainfall absorbed by tree roots and therefore kept out of storm sewers is equal to 42 Olympic sized pools!** 

<sup>9</sup> Benefits are based on USDA Forest Service research and are meant for guidance only. Visit [www.itreetools.org](http://www.itreetools.org) to learn more. Get more data at [i-Tree Landscape!](#)

## 7.0 Conclusions and Initial Implementation Action Plan

### 7.1 Recommendations for Future GHG Emission Inventories

To improve the GHG inventory for City operations, Fishbeck proposes the following recommendations:

- Implement a process for better verification of mileage entered for City-owned vehicles.
- Collect vehicle make and model data for employees using personal or other non-City controlled vehicles for business travel.
- Request refrigerant replacement data from HVAC maintenance contractors.
- Begin to develop a Community-wide GHG inventory which includes public participation.

### 7.2 Recommendations for GHG Emission Reductions

As the goal of this process is to set a City baseline to be used for future GHG reduction tracking, following are potential areas for the City to consider for GHG emission reductions :

- City-owned and operated buildings are responsible for more than 30% of the total emissions. Recommendations for building energy reductions include:
  - Establish an exhaust fan control strategy and obtain control by setpoint adjustments, control modifications, and rewiring where necessary. Generally, exhaust and make up air systems use excess energy due to lack of controlled operation.
  - Reduce excessive lighting in buildings with foot candle levels above the recommended level of 35, as long as it is appropriate for the activities in a particular facility.
  - Replace aging light fixtures with LED or modern fluorescent systems.
  - Establish minimum design and energy efficiency construction requirements for all new and renovated City buildings.
  - Keep exterior fixtures free of bug debris to provide more light and to dissipate fixture heat.
  - Evaluate demand and capacity of domestic hot water systems in buildings to facilitate optimization.
  - Install aerators in lavatory faucets to reduce flow.
- For City fleet vehicles, as replacement opportunities arise, and the infrastructure exists or can be installed to support it, alternative fuel vehicles should be considered,<sup>10</sup> including:
  - **Biodiesel** – Sustainable Biodiesel is a clean burning, renewable alternative fuel produced from vegetable oils or animal fats and which can be blended with petroleum diesel to create a biodiesel blend.
  - **Ethanol** – Sustainable Ethanol can be blended with gasoline in varying quantities. E85, a mixture of 85% ethanol and 15% unleaded gasoline, is an alternative fuel for use in flexible fuel vehicles.
  - **Electricity** – Vehicles that run on electricity have no tailpipe emissions.
  - **Compressed Natural Gas** – Natural gas that is extracted from wells and compressed. Natural gas vehicles have been found to produce fewer GHG emissions than gasoline vehicles.
  - **Hydrogen<sup>11</sup>** – Hydrogen Fuel Cells is a renewable alternative fuel that can be used to create electricity with the only resulting emission being water vapor.
- Use of low-rolling resistance tires in larger City fleet trucks.
- Use of conference calling and video meetings in lieu of travel for routine meetings.

<sup>10</sup> CDP Recommends – Organizations *should put in place a biofuels strategy, which includes long-term targets on the use of biofuels and definitions of what they consider sustainable biofuel. Companies should assess the local and regional context to determine what biofuels are most appropriate for their needs. Factors influencing their decisions could include market availability, preferences for local production, and other sustainability considerations. Finally, any sustainability-related requirements should be included in biofuel supplier contracts where possible.*

<sup>11</sup> Producing hydrogen is energy intensive and may come from cracking natural gas (Grey or Blue Hydrogen). For sustainability purposes, Green Hydrogen, which is produced by passing electricity generated from renewable sources through water, results in low carbon emissions.

## Emission Factors for Greenhouse Gas Inventories

Last Modified: 12 September 2023

**Blue text indicates an update from the 2022 version of this document.**

Typically, greenhouse gas emissions are reported in units of carbon dioxide equivalent (CO<sub>2</sub>e). Gases are converted to CO<sub>2</sub>e by multiplying by their global warming potential (GWP). The emission factors listed in this document have not been converted to CO<sub>2</sub>e. To do so, multiply the emissions by the corresponding GWP listed in the table below.

Gas	100-Year GWP
CH <sub>4</sub>	25
N <sub>2</sub> O	298

Source: Intergovernmental Panel on Climate Change (IPCC), Fourth Assessment Report (AR4), 2007. See the source note to Table 11 for further explanation.

Notes:

Emission factors are per unit of heat content using higher heating values (HHV). If heat content is available from the fuel supplier, it is preferable to use that value. If not, default heat contents are provided. The factors represented in the table above represent combustion emissions only (tank-to-wheel) and do not represent upstream emissions or well-to-wheel emissions.

**Table 2 Mobile Combustion CO<sub>2</sub>**

Fuel Type	kg CO <sub>2</sub> per unit	Unit
Aviation Gasoline	8.31	gallon
Biodiesel (100%)	9.45	gallon
Compressed Natural Gas (CNG)	0.05444	scf
Diesel Fuel	10.21	gallon
Ethanol (100%)	5.75	gallon
Kerosene-Type Jet Fuel	9.75	gallon
Liquefied Natural Gas (LNG)	4.50	gallon
Liquefied Petroleum Gases (LPG)	5.68	gallon
Motor Gasoline	8.78	gallon
Residual Fuel Oil	11.27	gallon

Source: Federal Register EPA: 40 CFR Part 98, e-CFR, (see link below), Table C-1 (78 FR 71950, Nov. 29, 2013, as amended at 81 FR 89252, Dec. 9, 2016)  
<https://www.ecfr.gov/current/title-40/chapter-I/subchapter-C/part-98>

Notes: The factor was developed based on the CO<sub>2</sub> factor for Natural Gas factor and LNG fuel density from GREET1\_2022.xlsx Model, Argonne National Laboratory (Fuel\_Specs worksheet). The factors represented in the table above represent combustion emissions only (tank-to-wheel) and do not represent upstream emissions or well-to-wheel emissions.

Source: EPA eGRID2021, February 2023 (Table 1. Subregion Output Emission Rates)

<https://www.epa.gov/eGRID/download-data>

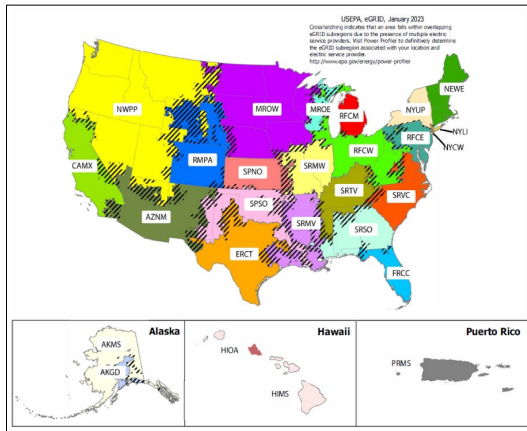

**Notes:**

Total output emission factors can be used as default factors for estimating GHG emissions from electricity use when developing a carbon footprint or emissions inventory. Annual non-base-load output emission factors should not be used when developing a carbon footprint or emissions inventory, but can be used to estimate GHG emissions reductions on the grid from changes in electricity use.

For technical information, reference the EPA's eGRID Technical Guide

[https://www.epa.gov/system/files/documents/2023-01/eGRID2021\\_technical\\_guide.pdf](https://www.epa.gov/system/files/documents/2023-01/eGRID2021_technical_guide.pdf)

The factors represented in the table above represent combustion emissions only (tank-to-wheel) and do not represent upstream emissions or well-to-wheel emissions.

**Table 7 Steam and Heat**

	CO <sub>2</sub> Factor (kg / mmBtu)	CH <sub>4</sub> Factor (g / mmBtu)	N <sub>2</sub> O Factor (g / mmBtu)
Steam and Heat	66.33	1.250	0.125

**Notes:**

Emission factors are per mmBtu of steam or heat purchased. These factors assume natural gas fuel is used to generate steam or heat at 80 percent thermal efficiency. The factors represented in the table above represent combustion emissions only (tank-to-wheel) and do not represent upstream emissions or well-to-wheel emissions.

**Scope 3 Emission Factors**

Scope 3 emission factors provided below are aligned with the Greenhouse Gas Protocol Technical Guidance for Calculating Scope 3 Emissions, version 1.0 (Scope 3 Calculation Guidance). Where applicable, the specific calculation method is referenced. Refer to the Scope 3 Calculation Guidance for more information (<http://www.ghgprotocol.org/scope-3-technical-calculation-guidance>)

**Table 8 Scope 3 Category 4: Upstream Transportation and Distribution and Category 9: Downstream Transportation and Distribution**

These factors are intended for use in the distance-based method defined in the Scope 3 Calculation Guidance. If fuel data are available, then the fuel-based method should be used, with factors from Tables 2 through 5.

Vehicle Type	CO <sub>2</sub> Factor (kg / unit)	CH <sub>4</sub> Factor (g / unit)	N <sub>2</sub> O Factor (g / unit)	Units
Medium- and Heavy-Duty Truck	1.387	0.013	0.038	vehicle-mile
Passenger Car <sup>A</sup>	0.313	0.008	0.007	vehicle-mile
Light-Duty Truck <sup>B</sup>	0.467	0.013	0.012	vehicle-mile
Medium- and Heavy-Duty Truck <sup>C</sup>	0.170	0.0016	0.0047	ton-mile
Rail	0.021	0.0016	0.0005	ton-mile
Waterborne Craft	0.044	0.0254	0.0011	ton-mile
Aircraft	0.698	0	0.0215	ton-mile

**Source:**

CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O emissions data for road vehicles are from Table 2-13 of the EPA (2022) Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2020.

Vehicle-miles and passenger-miles data for road vehicles are from Table VM-1 of the Federal Highway Administration Highway Statistics 2020.

CO<sub>2</sub>e emissions data for non-road vehicles are based on Table A-107 of the EPA (2022) Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2020, which are distributed into CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O emissions based on fuel/vehicle emission factors.

Freight ton-mile data are from Table 1-50 of the Bureau of Transportation Statistics, National Transportation Statistics for 2021 (2020 data).

**Notes:**

Vehicle-mile factors are appropriate to use when the entire vehicle is dedicated to transporting the reporting company's product. Ton-mile factors are appropriate when the vehicle is shared with products from other companies.

The factors represented in the table above represent combustion emissions only (tank-to-wheel) and do not represent upstream emissions or well-to-wheel emissions.

<sup>A</sup> Passenger car: includes passenger cars, minivans, SUVs, and small pickup trucks (vehicles with wheelbase less than 121 inches).

<sup>B</sup> Light-duty truck: includes full-size pickup trucks, full-size vans, and extended-length SUVs (vehicles with wheelbase greater than 121 inches).

<sup>C</sup> Medium- and Heavy-Duty Truck: includes Combination Trucks and single frame trucks that have 2-Axes and at least 6 tires or a gross vehicle weight rating exceeding 10,000 lbs.

**Table 9 Scope 3 Category 5: Waste Generated in Operations and Category 12: End-of-Life Treatment of Sold Products**

These factors are intended for use in the waste-type-specific method or the average-data method defined in the Scope 3 Calculation Guidance for category 5 and category 12. Choose the appropriate material and disposal method from the table below. For the average-data method, use one of the mixed material types, such as mixed MSW.

Material	Metric Tons CO <sub>2</sub> e / Short Ton Material					
	Recycled <sup>d</sup>	Landfilled <sup>b</sup>	Combusted <sup>c</sup>	Composted <sup>d</sup>	Anaerobically Digested (Dry Digestate with Curing)	Anaerobically Digested (Wet Digestate with Curing)

Source: EPA, Office of Resource Conservation and Recovery (February 2016) Documentation for Greenhouse Gas Emission and Energy Factors used in the Waste Reduction Model (WARM). Factors from tables provided in the Management Practices Chapters and Background Chapters. WARM Version 15, November 2020 Update. Additional data provided by EPA, WARM-15 Background Data.

Notes: These factors do not include any avoided emissions impact from any of the disposal methods. All the factors presented here include transportation emissions, which are optional in the Scope 3 Calculation Guidance, with an assumed average distance traveled to the processing facility. AR4 GWPs are used to convert all waste emission factors into CO<sub>2</sub>e.

<sup>a</sup> Recycling emissions include transport to recycling facility and sorting of recycled materials at material recovery facility.

<sup>b</sup> Landfilling emissions include transport to landfill, equipment use at landfill and fugitive landfill CH<sub>4</sub> emissions. Landfill CH<sub>4</sub> is based on typical landfill gas collection practices and average landfill moisture conditions.

<sup>c</sup> Combustion emissions include transport to combustion facility and combustion-related non-biogenic CO<sub>2</sub> and N<sub>2</sub>O.

<sup>d</sup> Composting emissions include transport to composting facility, equipment use at composting facility and CH<sub>4</sub> and N<sub>2</sub>O emissions during composting.

**Table 10 Scope 3 Category 6: Business Travel and Category 7: Employee Commuting**

These factors are intended for use in the distance-based method defined in the Scope 3 Calculation Guidance. If fuel data are available, then the fuel-based method should be used, with factors from Tables 2 through 5.

Vehicle Type	CO <sub>2</sub> Factor (kg / unit)	CH <sub>4</sub> Factor (g / unit)	N <sub>2</sub> O Factor (g / unit)	Units
Passenger Car <sup>a</sup>	0.313	0.008	0.007	vehicle-mile
Light-Duty Truck <sup>b</sup>	0.467	0.013	0.012	vehicle-mile
Motorcycle	0.178	0.111	0.019	vehicle-mile
Intercity Rail - Northeast Corridor <sup>c</sup>	0.058	0.0055	0.0007	passenger-mile
Intercity Rail - Other Routes <sup>c</sup>	0.150	0.0117	0.0038	passenger-mile
Intercity Rail - National Average <sup>c</sup>	0.113	0.0092	0.0026	passenger-mile
Commuter Rail <sup>d</sup>	0.135	0.0109	0.0027	passenger-mile
Transit Rail (i.e. Subway, Tram) <sup>e</sup>	0.096	0.0080	0.0011	passenger-mile
Bus	0.055	0.0063	0.0011	passenger-mile
Air Travel - Short Haul (< 300 miles)	0.207	0.0064	0.0066	passenger-mile
Air Travel - Medium Haul (>= 300 miles, < 2300 miles)	0.129	0.0006	0.0041	passenger-mile
Air Travel - Long Haul (>= 2300 miles)	0.163	0.0006	0.0052	passenger-mile

Source: CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O emissions data for highway vehicles are from Table 2-13 of the EPA (2022) Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990–2020.

Vehicle-miles and passenger-miles data for highway vehicles are from Table VM-1 of the Federal Highway Administration Highway Statistics 2020.

Fuel consumption data and passenger-miles data for rail are from Tables A.14 to A.16 and C.9 to C.11 of the Transportation Energy Data Book: Edition 40. Fuel consumption was converted to emissions by using fuel and electricity emission factors presented in the tables above.

Intercity Rail factors from communication with Amtrak, March 2020. These are based on 2019 values.

Air Travel factors from 2022 Guidelines to Defra / DECC's GHG Conversion Factors for Company Reporting. Version 2.0 June 2022.

**Notes:**

The factors represented in the table above represent combustion emissions only (tank-to-wheel) and do not represent upstream emissions or well-to-wheel emissions.

CH<sub>4</sub> and N<sub>2</sub>O emission factor updates for motorcycle and bus due to a methodology change.

<sup>a</sup> Passenger car: includes passenger cars, minivans, SUVs, and small pickup trucks (vehicles with wheelbase less than 121 inches).

<sup>b</sup> Light-duty truck: includes full-size pickup trucks, full-size vans, and extended-length SUVs (vehicles with wheelbase greater than 121 inches).

<sup>c</sup> Intercity rail: Amtrak long-distance rail between major cities. Northeast Corridor extends from Boston to Washington D.C. Other Routes are all routes outside the Northeast Corridor.

<sup>d</sup> Commuter rail: rail service between a central city and adjacent suburbs (also called regional rail or suburban rail).

<sup>e</sup> Transit rail: rail typically within an urban center, such as subways, elevated railways, metropolitan railways (metro), streetcars, trolley cars, and tramsways.

Global Warming Potentials

Source: 100-year GWPs from IPCC Fourth Assessment Report (AR4), 2007. IPCC AR4 was published in 2007 and is among the most current and comprehensive peer-reviewed assessments of climate change. AR4 provides revised GWPs of several GHGs relative to the values provided in previous assessment reports, following advances in scientific knowledge on the radiative efficiencies and atmospheric lifetimes of these GHGs and of CO<sub>2</sub>.

Factors in the 2023 Emission Factors update are based on AR4 GWPs, but EPA recognizes that Fifth Assessment Report (AR5) GWPs have been published and used in the Draft Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2021 report (published February 2023). However, this 2023 Emission Factors Hub and the GHG Reporting Program continue to use AR4 GWPs. EPA plans to incorporate AR5 GWPs into the 2024 Emission Factors Hub update.
